² Submission Policy Assignment Project Exam Help

You need to submit a lab report (one single PDF file) to describe what you have done and what you have observed with screen shots whenever necessary, you also need to provide explanation or codes to he sole with a fart rulation of the street of the sole with a fart rulation of the sole what you have done and you have done and what you have done and what you have done and you have done and what you have done and you have do

All source code if required should be embedded in your report. In addition, if a demonstration video is required, you should record your screen demonstration with your voice explanation and upload the video of the video should be mentioned in your report wherever required. You can use this free tool to make the video: https://monash-panopto.aarnet.edu.au/; other tools are also fine. Then, please upload the PDF file to Moodle. Note: the assignment is due on October 19th, 2019, Saturday, 11:59:59 (Firm!).

Late submission penalty: 10-point deduction per day. If you require a special consideration, the application should be submitted and notified at least three days in advance. Zero tolerance on plagiarism: If you are found cheating, penalties will be applied, i.e., a zero grade for the unit. The demonstration video is also used to detect/avoid plagiarism. University polices can be found at https://www.monash.edu/students/academic/policies/academic-integrity

3 Environment Setup

In this section, you need to double check whether you have configured the network adapter for the virtual machine that you have downloaded in Lab Week 7. If you have downloaded and used the VM during Lab Week 7, you can re-use it and open three different terminals in the VM to log into server, client, and attacker containers. Otherwise, if you just download the VM for the first time, you need to follow Section 1—Environment Setup in the Lab Week7(https://lms.monash.edu/pluginfile.php/9348018/mod resource/content/0/Week 7 Network

4 TCP Attack y [40 Marks]

The Transmission (P) is a core protocol of the Internet protocol suite. It sits on top of the IP reliable and ordered communication channel between applications running on network a computers. TCP is in a layer called Transport layer, which provides host-to-host communication services for applications. To achieve such reliable and order communication, TCP requires both ends of a communication to maintain a connection. Unfortunately, when VP was devadped in Security machinism was built into this protocol, making it possible for attackers to eavesdrop on connections, break connections or hijack connections. In this section, you are required to perform these attacks using Scapy—a packet manipulation tool for computer networks written in Python. You can find more examples how to construct TCP packets with Scapy in Appendix 7.3.

4.1 Task 1: TCP Reset Attacks 115 Marks ASS1 2 Innacial tution test beauto the lp

In the stream of packets of a TCP connection, each packet contains a TCP header. In the header, there is a bit known as the "reset" (RST) flag. In most packets, this bit is set to 0 and has no effect; however, if the present the present that the reserver should immediately stop using the TCP connection. That means it should not send back any more packets using the connection's identifying numbers, called ports, and discard any further packets with headers belong to that connection. A TCP reset basically kills a TCP connection instantly.

Material in later terms and the content of the cont

It is possible for a third computer (aka attacker) to monitor the TCP packets on the connection and then send a "forged" packet containing a TCP reset to one or both endpoints. The headers in the forged packet must indicate, falsely, that it came from an endpoint, not the forger. This information includes the endpoint IP addresses and port numbers. Every field in the IP and TCP headers must be set to a convincing forged value for the fake reset to trick the endpoint into closing the TCP connection.

The idea is quite simple: to break up a TCP connection between A and B, the attacker just spoofs a TCP RST packet from A to B or from B to A.

Q1: Connect from client (container) to server (container) using SSH (from client terminal execute ssh 10.4.1.15), the username and password are same: client. Perform TCP RST attack, from attacker (container), on SSH service using Scapy (python-based) packet generator. The client terminal should show the connection is terminated. Please submit your python code and the steps, along with screenshots, you have taken to perform the attack. (Python code: 5 marks, explanation and screenshots: 5 marks)

Hint: You can refer to a scapy example located in /root/reste.py in the **attacker** container to have a better understanding how to construct a reset TCP packet.

Q2: Briefly explain the TGP RST attack and propose at least two theoretical countermeasures.

You do not have to the any configuration implementation for this task.

(Explanation: 2.5 marks, countermeasures: 2.5 marks)

4.2 Task 2: TCP 4.2 Task 2: Marks]

Once a TCP client the three-way handshake protocol, a connection is established, and we the three-way handshake protocol, a connection is established, and we the transport of the three-way handshake protocol, a connection is established, and we the transport of the three-way handshake protocol, a connection is established, and we the transport of the three-way handshake protocol, a connection is established, and we then the transport of the three-way handshake protocol, a connection is established, and we then the three-way handshake protocol, a connection is established, and we the transport of the three-way handshake protocol, a connection is established, and we the three-way handshake protocol, a connection is established, and we the transport of the three-way handshake protocol, a connection is established, and we the transport of the trans

WeChat: cstutorcs

We call these four fields as the signature of a TCP session. As we have already learned, spoofing packets is not difficult. What if we spoof a TCP packet, whose signature matches that of an existing TCP session on the target machine D will this packet be accepted by the larget? Clearly, if the above four elements match with the signature of the session, the receiver cannot tell whether the packet comes from the real sender or an attacker, so it considers the packet as belonging to the session.

Assignmachtultores les anothelp

However, for the packet to be accepted, one more critical condition needs to be satisfied. It is the TCP sequence number. TCP is a connection-oriented protocol and treats data as a stream, so each octet in the process of the process of the contains a 32-bit sequence number, identifying its position in the stream. The TCP heater contains a 32-bit sequence number field, which contains the sequence number of the first octet in the payload. When the receiver gets a TCP packet, it places the TCP data (payload) in a buffer; where exactly the payload is placed inside the buffer depends on the sequence number. The table of the payload is placed inside the buffer depends on the sequence number. The table of the payload is placed inside the buffer depends on the sequence number in the buffer using the correct order.

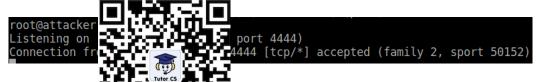

The objective of this task is to hijack an existing TCP connection (session) between client and server by injecting malicious contents into their session.

Q3: Connect TELNET from client to server (from client terminal execute *telnet 10.4.1.15*), the username and password are same: *client*. Write a python code, using scapy, which can inject packets in the client-server telnet communication, the goal is to make a directory called "attacker" at the server (as seen in the screenshot below). You can use attacker container to run the python code. Submit python code and steps, along with screenshots, you have taken to perform the attack. (Python code: 5 marks, steps with screenshots: 5 marks)

root@server:~# ls attacker

Q4: Connect TELNET from **client** to **server** (from **client** terminal execute **telnet** 10.4.1.15), the username and password are same: **client**. The objective is to get a reverse shell from **server**. Reverse shell is a shell process running on a remote machine, connecting back to the attacker's machine. We are omitting the details of reverse shell and encourage students to research about it, you can start from here (here (https://hackernoon.com/reverse-shell-cf154dfee6bd). Write a

python code, using Scapy, which can inject packets in client-server telnet communication and create a reverse shell from server, which connects lack to attacker (as set in the screenshot below). Submit python code and steps, along with screenshots, you have taken to perform the attack. (Python code: 5 marks, steps with screenshots 5 marks)

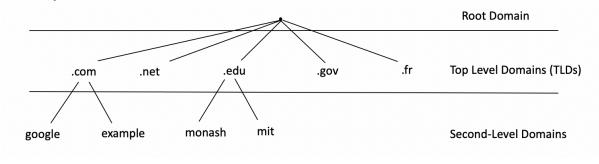

(Python Code and Steps / Unsuccessful reason: 5 marks)

5 DNS Attack Assignment Project Exam Help

Domain Name System (DNS) is an essential component of the Internet infrastructure. It serves as the phone Social internet in the principal component of the Internet infrastructure. It serves as the phone Social internet in the principal component of the Internet infrastructure. It serves as the phone Social internet in the Internet infrastructure in the Internet infrastructure in the Internet infrastructure. It serves as the phone Social internet infrastructure infrastructure in the Internet infrastructure. It serves as the phone Social internet infrastructure infrastructure in the Internet infrastructure infrastructure. It serves as the phone Social internet infrastructure infrastructure infrastructure. It serves as the phone Social infrastructure infrastructure infrastructure. It serves as the phone Social infrastructure infrastructure infrastructure. It serves as the phone Social infrastructure infrastructure infrastructure. It serves as the phone Social infrastructure infrastructure infrastructure infrastructure. It serves as the phone Social infrastructure infrastr

Due to the large number of computers and networks on the Internet, the domain namespace is organised in a hierarchy three-life tructures large the tree is called a domain or subdomain when referencing to its parent node. The following figure depicts a part of the domain hierarchy.

The domain hierarchy tree structure describes how the domain namespace is organised, but that is not exactly how the domain name systems are organised. Domain name systems are organised according to zones. A DNS zone basically groups contiguous domains and subdomains on the domain tree, and assign the management authority to an entity. Each zone is managed by an authority, while a domain does not indicate any authority information. The following figure depicts an example of the example.com domain.

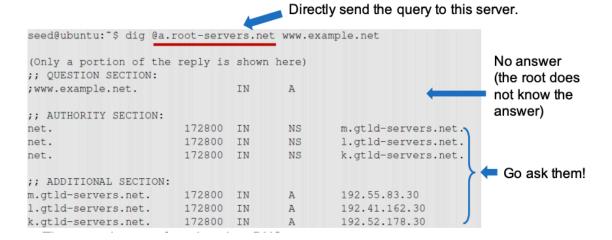

WeChat: cstutores

Assume that example com in the above figure is an international company, with branches all over the world, so the company's domain is further divided into multiple sub-domains, including usa.example.com, uk.example.com, and france.example.com. Inside US, the usa sub-domain is further divided by the light standard for the call of the company.

Each DNS zone has at least one authoritative nameserver that publishes information about that zone. The grant of the property of the provide the original and definitive answers to DNS queries, as opposed to obtaining the answers from other DNS servers.

With such arrangement provided by the authority is for each of its subdomains. By doing this, it maintains the independence among the branches in different countries and enable the administrative right of those subdomains, so the branch in each countries are the countries and enable the administrative right of those subdomains, so the branch in each countries are the countries and enable the administrative right of those subdomains, so the branch in each countries are the countries are the countries and enable the administrative right of those subdomains.

For a given DNS query, if your local DNS server does not the answer, it will ask other DNS servers on the Internet for answer via hierarchical authority servers. The following example demonstrates a dig (DNS query) for the domain www.example.net when sending the query directly to one of the root server (i.e. a.root-servers.net).

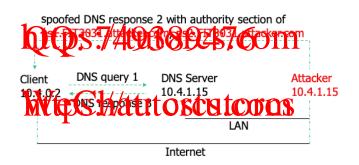

There are four types of sections in a DNS response: *question section*, *answer section*, *authority section*, and *additional section*. From the above result, we can see that the root server does not

know the answer (because the reply does not include an answer section, but it tells several authoritative nameservers touched net zone (the Ni records in the authoritative nameservers), along with their IP address if possible in the additional section). If you continuously dig the domain www.example.net on one these authoritative nameservers, you will finally end up with the answer section standard process of the machine hosting the website for www.example.net.

When your local large formation from other DNS servers, it caches the information, so if the servers is needed, it will not waste time to ask again.

5.1 Task 3: Local rgeting Authority Nameserver [20 Marks]

We recalled that a DNS response contains question section, answer section, authority section, and additional section level play target the authority section, the attack only affects one hostname. Real DNS attacks usually target the authority section by providing a fake NS record for the target domain in the authority section. If the fake NS record is cached, when the victim local DNS server tries to find any IP address in the target domain, it will send a request to the malicious nameserver specifical in the target domain. In this task, you will explore how to target the authority server of example.net and manage to replace it with "ns1.FIT3031.attacker.com" and "ns2.FIT3031.attacker.tom" and "ns2.FIT3031.attacker.tom" and "server to the target domain in the target domain.

Hint: You always need to run the CORE simulation with the simulation file FIT3031.imm (the file located in the VM's desktop) so that the network simulation can be run and connected with Internet. Then, to achieve the task, you should run another terminal from server container to simulate the attacker who is in the same LAN network. You should also flush the DNS server's cache to refresh the DNS query response. In addition, you can review the existing script spoof_dns.py that has already been included in the server container at /root/spoof_dns.py. The script currently has demonstrated how to spoof the answer section when constructing forged DNS packet response. You can also find more examples how to construct DNS packets with Scapy in Appendix 7.3. Other commands including flushing DNS server's cache and restart DNS server can also be found in Appendix 7.2.

Q6: Submit your python code and steps to perform the directly spoofing DNS attack that modifies the authority server of example.net to be "ns1.FIT3031.attacker.com" and "ns2.FIT3031.attacker.com. (**Python code: 10 marks**). If the attack works, you should see the result as in following figures for which the malicious authoritative servers are taken place.

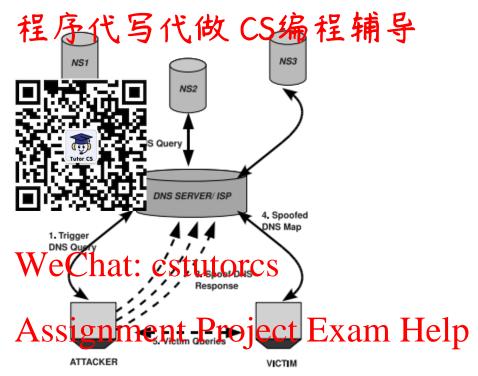

Q7: Provide your explanation and evidence (snapshots) to support your directly spoofing DNS attacks above. (Explanation in a large state of the stat

5.2 Task 4: Remote by Attack targeting Authority Server [40 Marks]

The previous local DNS attacks essume the attacker and the DNS victim server are on the same LAN so that she callocker the first lates Lates ago and leply with a forged DNS packet. When the attacker and the DNS server are not on the same LAN, the attack becomes harder since the attacker cannot see the DNS query. When the DNS victim server cannot resolve the DNS query, it will for tart the DNS query is sent via a UDP packet where the UDP's source port is a 16-bit random number. In addition, the 16-bit transaction ID in the DNS header is also self-created by the DNS victim server. Hence, if the remote attacker wants to forge the DNS response, the forged packet must contain the correct values of these two numbers; otherwise, the reply will not be accepted.

Without being able to sniff the query packet, the remote attacker can only guess these two numbers. The chance is one out of 2^{32} for each guess. If an attacker can send out 1000 spoofed responses, it may take several days to try up 2^{32} time. In contrast, it only takes few seconds to receive the correct packet response from the forwarder Google DNS. Consequently, that real reply will be cached by the local DNS victim server. To make another try, the attacker has to wait for the server to send out another DNS query when its cache times out. Hence, this attacking chance makes the remote DNS attack unrealistic.

The remote DNS attack had become an open problem until Dan Kaminsky came up with a simple solution in 2008. The attack is depicted in the following figure.

Assi Ennacht Project Examo Help

We choose a domain **test.com** as our targeted domain name in this task. The attacker wants to cause the DNS server (10.4.1.15) to use her DNS server (ns.FIT3031.attacker.com) when client (10.4.0.2) query the DNS server (for every test com. The following steps with reference to above figure describe the cattline of the attack.

- 1. The attacker queries the DNS server for a non-existing name in **test.com**, for example xyz123.test. The attacker queries the DNS server for a non-existing name in **test.com**, for example xyz123.test.
- 2. Since the mapping resolution cannot be resolved by the DNS server's cache, the server forwards the query to Google DNS (8.8.8.8) for that name resolution.
- 3. In the meantime, the attacker floods the DNS server with many spoofed DBS responses, each trying a different transaction ID and source port number (hoping one guess is correct). In that forged response, not only the attacker provides the IP resolution for the hostname xyz123.test.com, but also provides an authority name server for the domain test.com.

Even if the response failed, the attacker will go back step one, and try another non-existing random name until the attacker succeeds.

4. Once the attack succeeds, when the client sends a DNS query to the poisoned DNS server for **www.test.com**, the nameserver returned by the DNS server will actually be set by the attacker.

To simplify and shorten the attack's simulation time in this task, we suggest you follow the below steps before doing the task.

- 1. Double check the IP addresses of the server, attacker, and client to ensure the server and the attacker are not in the same LAN to inglife or fair or in the server.
 - o **DNS server**: 10.4.1.15
 - Remote attacker: 10.0.0.2 (you should use the attacker's terminal after logging to the wind to the wind to the wind to locate attacker -- bash
- 2. In the **DNS** (u can type the following command to configure DNS /etc/bind/named.conf.options

Then, you shall all the July Soundary Google DNS's forwarder 8.8.4.4 and fix the query source port of the DNS server (i.e. 33333). With this constraint, the attacker now only needs to guess the transactionID of the DNS packet when performing remote DNS attacks. You was every like following figure for the correct configuration of DNS server. In the figure, you can see that the forwarder 8.8.4.4 has been commented and query-source port 33333 has been added.

```
Assignment Project Exam Help

directory "/var/cache/bind";

// if there is a firewall between ou and names vers you vant
// to the is a firewall between ou and names vers you vant
// ports to talk. See http://www.kb.cert.org/vuls/id/800113

// If your ISP provided one or more IP addresses for stable
// nameservers, you probably/want to use them as forwarders.
// Uncomment it to body your to use them as forwarders.
// Uncomment it to body your to use them as forwarders.
// the all-0's placeholder.

recursion yes;
allow-recursion (any; ):
// state of the interest of the direct of the d
```

3. After making the changes in the above step, you should restart your DNS server by using the following command

sudo systemctl restart bind9

4. In this step you need to configure the nameserver of the **attacker** to be the victim DNS server, so that the attacker can send and flood DNS queries to that server. In the **attacker's** terminal, you can type

sudo nano /etc/resolvconf/resolv.conf.d/head and then comment out Google DNS server's and add "nameserver 10.4.1.15" like the following figure, then save the configuration file by using Ctrl+O

We provide you the **reporte** day, yeaript template that helps to perform the Kaminsky attack. You can download this template from Moodle and then later modify the template to perform the attack. The template presents what you need to do through each. You can develop this python script and upload it to your attacker container later, or you can upload this template to the container first and nodify interprising purpo by redirecting tools x Appendix 7.1 contains some useful commands that may help you know to how to upload/pull files from your VM to the containers and vice versa. Below is the task breakdown to help you gain the marks.

Q8: You need to complete Step 1 in the remote_dns.py to create 10000 dummy hostnames. (The screenshot of your Python code for this step: 5 marks)

Q9: You need to contribute of the screenshot of your Python code for this step: 5 marks)

Q10: You need to with the state of the state

- A randomly generated transaction ID for DNSpkt. (5 marks for code and screenshot)
- The malicious DNS server "ns.FIT3031.attacker.com" is included in the nameserver authority for the domain test.com when you construct DNSpkt. (10 marks for code and screenshot)
- *Additional section* showing "ns.FIT3031.attacker.com" has the IP of the attacker 10.0.0.2. (**5 marks for code and screenshot**)

Q11: Provide your video demonstration evidence to support and verify that you have performed the attack and it worked successfully. You need to upload your demo video to your Monash Google Drive and embed its shared link to your report so that the teaching team can view and verify your works. In the video, you need to demonstrate following key points:

• Wireshark traffic captured on the Gateway on *eth1* shows the transactionID in DNS packet sent by the victim DNS server to Google, and the correctly matched transaction ID in the forged packet sent by the attacker to the victim DNS server. (5 marks for your explanation during the demonstration video)

From client's terminal, you send DNS query for www. test.com, and then the terminal shows "ns.FITBELL'attacker com in the lathor to worth for the lithan test.com. (5 marks for your explanation during the demonstration video)

Hint: You always ne ■ \blacksquare simulation with the FIT3031.imm (the file located in ulation can be run and connected with Internet. When s turn on Wireshark monitor on eth1 on Gateway to server to support your evidence in Q11. If you launch the VM's desktop) sc you launch the attact capture the traffic b 🚅 following figures.
